(Dated: February 7, 2008)

We report on a high-statistics search for the $\Theta(1540)^+$ resonance in $\Sigma^-$-nucleus collisions at 340 GeV/c. No evidence for this resonance was found in our data sample which contains 13 millions $K^{-}_0 \rightarrow \pi^+ \pi^- \pi^-$ decays above background. For the decay channel $\Theta^+ \rightarrow K^0_s p$ and the kinematic range $x_F > 0.05$ we find the production cross section to be $BR(\Theta^+ \rightarrow K^0_s p) \cdot \sigma_0 < 1.8 \mu b$ per nucleon at 90% CL.

PACS numbers: 13.85.-t, 13.85.Rm, 25.80.Pw

During the last years twelve experimental groups have reported evidence for a narrow baryonic resonance in the KN channel at a mass of about 1540 MeV/c$^2$, 12. While the number of positive observations seems to be quite convincing, when plotting the data points with error bars but without background curves to guide the eye it becomes obvious that the limited statistics is a common drawback of the individual observations. It is remarkable that the event statistics is nearly independent of the experimental situation and it is disturbing that the peak positions differ significantly in the various experiments. On the other hand at least 11 experiments have reported negative search results 13, 14. Figure 1 shows a collection of the first nine published results which gave evidence for the existence of the so called $\Theta(1540)^+$. During the last years twelve experimental groups have reported evidence for a narrow baryonic resonance in the KN channel at a mass of about 1540 MeV/c$^2$. mentum spread of particles with a mean momentum of 340 GeV collected in the years 1993 and 1994. The beam pions were strongly suppressed at the trigger target, the field-free decay zone of about 10 m length for hyperons, and a reconstructed interaction vertex in the targets and the decay vertex in the decay zone. Λ candidates with a reconstructed mass within ±2σm(Λ) of the Λ mass (σm(Λ) was 1.8 MeV/c² at low momenta and 2.8 MeV/c² at 200 GeV/c). This requirement reduced the K⁰ sample by 3% and the background by 1/3.

The reconstructed π⁺π⁻ mass distribution of the remaining K⁰ candidates is shown in fig. 2. The peak from K⁰ decays contains about 13 million events, their momentum spectrum extends from 10 GeV/c to about 200 GeV/c. Above this momentum, very few K⁰ are left, and they do not contribute to K⁰p effective masses below 1570 MeV/c². The mass resolution is σm(K⁰) = 4 MeV/c² at low momenta and increases to σm(K⁰) = 7 MeV/c² at 200 GeV/c. Candidates with a reconstructed π⁺π⁻ mass within ±2σm of the K⁰ mass were retained for further analysis.

A ring-imaging Cherenkov counter placed downstream of the spectrometer magnet provided particle identification. It was followed by a leadglass electromagnetic calorimeter and an iron/scintillator hadron calorimeter, which were not used in this analysis.

K⁰ were reconstructed in the decay K⁰ → π⁺π⁻, using all pairs of positive and negative particles which formed a decay vertex in the decay zone. Λ → pπ⁻ decays with decay particle momenta corresponding to K⁰ → π⁺π⁻ decays can produce a spurious mass peak at 1540 MeV/c², if a mirror image of the decay proton is used in the search for K⁰p decays [14, 31]. To avoid this, we excluded K⁰ candidates with a reconstructed pπ⁻ mass within ±2σm(Λ) of the Λ mass (σm(Λ) was 1.8 MeV/c² at low momenta and 2.8 MeV/c² at 200 GeV/c). This requirement reduced the K⁰ sample by 3% and the background by 1/3.

The hyperon beam experiment WA89 at CERN ran from 1990 to 1994 in the West Hall. Its primary goal was the study of charmed particles and their decays. At the same time it collected a high statistics data sample of hyperons and hyperon resonances, among these Λ decays, and also K⁰ decays. We have already published the negative result of a search for the pentaquark candidate Φ(1860) [24, 25, 26, 27, 28, 29]. Facing such a situation, further high statistics searches for this resonance under different experimental conditions – e.g. different beam particles – are highly desirable.

The hyperon beamline selected negatively charged particles with a mean momentum of 340 GeV/c and a momentum spread of σ(p)/p = 9%. At the experimental target, the π⁻ to Σ⁻ ratio of the beam was about 2.3. The beam pions were strongly suppressed at the trigger level by a set of transition radiation detectors resulting in a remaining pion contamination of about 12%. In addition the beam contained small admixtures of K⁻ and Ξ⁻. The experimental target itself consisted of one copper slab with a thickness of 0.025 m in beam direction, followed by three carbon (diamond powder) slabs of 0.008 m each. The trajectories of incoming and outgoing particles were measured in silicon microstrip detectors upstream and downstream of the targets. Only events with a reconstructed interaction vertex in the targets and the surrounding counters were retained in the analysis.

The momenta of charged particles were measured in a magnetic spectrometer equipped with MWPCs and drift chambers. The spectrometer magnet was placed with its center 13.6 m downstream of the target, thus providing a field-free decay zone of about 10 m length for hyperons and K⁰ emerging from the target.

tons from Λ decays. The track had to be inside the acceptance of the RICH counter, which implies a momentum threshold at around 12 GeV/c. Since the proton threshold of the RICH was at 38 GeV/c we did not require proton identification, but rejected clearly identified π⁺ and K⁺ (thresholds at 5.5 and 20 GeV/c, resp.). From a study of reconstructed Λ decays, we determined that this requirement rejected 4% or less of genuine protons at all momenta, while the $K^0_s p$ candidate sample was reduced by a factor of 3.

The final $K^0_s p$ sample contained 5.2 million $K^0_s p$ candidates. Fig. 2 shows the $K^0_s p$ mass distribution of all candidates up to 2 GeV. No narrow signal is visible in this plot, neither did we see narrow signals around an invariant mass of 1540 MeV/c² in subsamples of $x_F$ or transverse momentum $p_t$. We define $x_F$ as $x_F = 2p_T^*/\sqrt{s}$, where $p_T^*$ is the $K^0_s p$ momentum component in beam direction in the beam-nucleon CMS and $\sqrt{s}$ is the invariant mass of the beam-nucleon system. In our case, $\sqrt{s} = 25.2$ GeV. The $x_F$ distribution is shown in fig. 3 for the $K^0_s p$ mass region between 1500 and 1560 MeV/c², it starts at $x_F = 0.05$ and thus covers part of the central production region.

Upper limits on the $K^0_s p$ pairs in the mass range 1500 MeV/c² to 1560 MeV/c², calculated separately for the copper and carbon targets, in bins of $x_F$ as listed in col. 1 of Table 1. We used four mass windows of 20 MeV/c² width, centered at 1520, 1530, 1540 and 1550 MeV/c², resp., for $i = 1, 2, 3, 4$, thus covering the full range of reported values for the $\Theta^+$ mass. The width was chosen taking into account our mass resolution, $\sigma_m(K^0_s p) = 4$ MeV/c², and the reported values for the intrinsic width of the $\Theta^+$. The observed number of $K^0_s p$ combinations in each mass window is $n_i$. From a fit to the observed $K^0_s p$ mass spectrum between 1460 and 1700 MeV/c² we calculated the expected non-resonant backgrounds $b_i$. Upper limits $n_{\text{max}}$ on the number of $\Theta^+ \rightarrow K^0_s p$ decays were then obtained by the formula $n_{\text{max}} = n_{\text{exp}}(\max(0, n_i - b_i) + 2\sqrt{b_i})$ and are listed in columns 2 and 5 of Tab. 1. These limits have a confidence level of 99% and scale approximately with the square root of the width of the search window.

Upper limits on the product of $BR$, the $\Theta(1540)^+ \rightarrow K^0_s p$ decay branching ratio, and the differential production cross sections $d\sigma_A/dx_F$ per nucleus are given in columns 3 and 6 of Tab. 1. Assuming the dependence of the cross section on the mass number to be $\sigma_A \propto \sigma_0 \cdot A^{2/3}$, where $\sigma_0$ is the cross section per nucleon, we finally obtained the limits on $BR \cdot d\sigma_0/dx_F$ in columns 4 and 7 of the table.

Limits on the integrated production cross sections $\sigma$ were calculated by summing quadratically the contributions $(d\sigma/dx_F)\cdot\Delta x_F$ in the nine individual $x_F$ bins. The results are $BR \cdot \sigma_A(x_F > 0.05) < 38$ and $<15 \mu$b per nucleon for the copper and carbon target, respectively. An extrapolation to the cross sections per nucleon yields the two values $BR \cdot \sigma_0(x_F > 0.05) < 2.4$ and $<2.9 \mu$b per nucleon. Since these are statistically independent upper limits, we can combine them to obtain $BR \cdot \sigma_0 < 1.8 \mu$b per nucleon for $\Theta(1540)^+ \rightarrow K^0_s p$ production by $\Sigma^-$ of 340 GeV/c in the region $x_F > 0.05$.

![FIG. 3: Invariant mass spectrum of all observed $K^0_s p$ candidates. The upper plot shows an extended view of the region around 1540 MeV/c². The statistical errors are approximately of the size of the dots.](image-url)

For a comparison of our result to observations of searches for the $\Theta(1540)^+$ we concentrate on hadronic reactions. It is interesting to note that all these experiments investigated the $K^\pm p$ decay channel, but only the SPHINX experiment searched in the $K^+n$ decay channel as well. Four experiments have reported observations of the $\Theta(1540)^+ [5-8]$. The COSY-TOF collaboration using a proton beam of 2.95 GeV/c and a liquid hydrogen target, has measured a production cross section $\sigma_0 = 30 - 120 \mu b$ per nucleon for $x_F > 0$. The SVD Collaboration using a $K^+$ beam of 0.85 GeV/c and a Xenon bubble chamber has not measured a cross section $\sigma_0$.

Negative search results were reported from at least 11 experiments $[13, 14, 15, 16, 17, 18, 20, 21, 22, 23]$. Out of these 6 experiments studied hadronic induced interactions $[13, 15, 16, 17, 18, 19]$. Usually these collaborations have compared their $\Theta^+$ production limits with their $\Lambda(1520)$ observations, and have obtained limits below 3% on the event or production ratio of $\Theta(1540)^+$ w.r.t. $\Lambda(1520)$. This we cannot do, although we do observe $\Lambda(1520)$ decays, because in our experiment two-body decay channels were suppressed in the trigger. We can, however, compare our result to the HERA-B result of $BR \cdot d\sigma/dx < 4 - 16 \mu b$ per nucleon at 95% CL for $\Theta^+$ masses between 1521 and 1555 MeV/c$^2$, at rapidity $y_{cm} \approx 0$. This value corresponds to $BR \cdot d\sigma/dx_F < 30 - 120 \mu b$ per nucleon, to be compared to our result $BR \cdot d\sigma/dx_F < 12 \mu b$ at 99% CL and for $0.05 < x_F < 0.15$ (this limit was obtained by combining the statistically independent carbon and copper target results).

If the $\Theta(1540)^+$ exists, as many experiments suggest, then the cross sections for $\Theta^+$ production in hadronic reactions at higher energies are surprisingly low compared to the production of hyperon resonances. This fact by itself could provide important information on the nature of the $\Theta(1540)^+$.

| $x_F$ | $\sigma_A | BR \cdot d\sigma/dx$ | $\sigma_0 | BR \cdot d\sigma/dx$ |
|------|-------------|-------------|
| 0.05 - 0.15 | 520 | 230 | 14.5 | 550 |
| 0.15 - 0.25 | 500 | 205 | 13.0 | 480 |
| 0.25 - 0.35 | 340 | 140 | 8.8 | 350 |
| 0.35 - 0.45 | 390 | 140 | 8.8 | 290 |
| 0.45 - 0.55 | 290 | 65 | 4.1 | 280 |
| 0.55 - 0.75 | 190 | 53 | 3.3 | 160 |
| 0.65 - 0.85 | 115 | 33 | 2.1 | 100 |
| > 0.85 | 35 | 11 | 0.7 | 45 |

$\sigma_A$ denotes cross sections per nucleus and per nucleon, respectively.

TABLE I: Upper limits on yields and cross sections. BR denotes the $\Theta(1540)^+ \rightarrow K^0 p$ decay branching ratio. $\sigma_A$ and $\sigma_0$ denote cross sections per nucleus and per nucleon, respectively.

[32] At large $x_F > 0.8$ we do however observe a broad ($\Gamma \simeq 90 \text{ MeV}/c^2$) resonance like structure at a mass of $\simeq 1750 \text{ MeV}/c^2$ which is possibly related to known $\Sigma^*$ resonances. A detailed analysis of this structure will be presented in a future paper.
